With the rapid evolution of liquid crystal display (LCD) television (TV), there is a large demand for developing high resolution, high color depth driver integrated circuits (ICs) [1- 3]. The panel of an LCD-TV is larger, and has higher definition, than that of a computer monitor. As a result, its color quality requires more accuracy.

TFT LCD is a variant of a liquid-crystal display (LCD) that uses thin-film-transistor (TFT) technology to improve image qualities such as addressability and contrast. A TFT LCD is an active matrix LCD, in contrast to passive matrix LCDs or simple, direct-driven LCDs with a few segments. In Arduino-based projects, the processor frequency is low.

Abstract. We developed an a7Si TFT?LCD panel with integrated gate driver circuit using a standard 57MASK process. To minimize the effect of the a7Si TFT current and LC's capacitance variation with temperature, we developed a new a7Si TFT circuit structure and minimized coupling capacitance by changing vertical architecture above gate driver circuit.

Typically, LCD panels have internal row and column drivers, much like DRAM. A row is selected by the row driver, then the column driver sequences through each of the columns. After each of the columns has been written, the row driver selects the next row and the process repeats. The VSYNC signal resets both row and column drivers to the upper left pixel. The HSYNC causes the row driver to step to the new row.
